Nystagms is an involuntary beating (webbling) movement of either one or both eyes. The eyes may 'webble' from side to side, up and down crotate slightly. There are different types of mystagms which have different causes.

It is usually non progressive (doesn't get wase). However, it is usually a lifelong condition

There are a number of causes of mystagmus. These cambe divided into two groups:

Sensory deprivation (an obstruction to vision leading to reduced vision)

Miopatric (no dearcause)

The commentative of nystagms is albinism (when the gene formulaing metaninis faulty). Nystagms is also quite often linked to having a squint

Nystagmus inearly childhood doesnit usually cause any symptoms.

Olderchildrennay notice that their vision is nit as clear as it could be

Adults and older children who developmy stagmus may get oscillopsia – this is when objects that are stationary appear to move side to side or shimmer:

Yourney notice that your child's mystagmus looks more noticeable if they have to wear arneye patch. Do not wony, this is temporary and will not make their mystagmus worse.

You may notice your childs mystagmus looks more noticeable if they are unwell or overtired and their vision may also become more bluned

Nystagmus cambe diagnosed by an Ophthalmologist or an Orthoptist, by observing your childs eyes as part of his/hereye examination

Your child may be referred for eye movement recording to determine the exact type of mystagmus they have. He or she may also be referred to the paediatrician

There is currently no specific treatment for mystagmus, however, if your child needs glasses them regular glasses updates can help improve their vision

Contact lenses may also help to reduce the wabble of your child's eyes. However, these can only be considered once your child is add enough to put contact lenses in by themselves.

Vision is usually affected by nystagmus. The amount that vision can be affected varies widely from person to person. Some children may have good vision whilst others may have quite reduced vision.

Insome cases glasses are required. If this is the case, they can help to improve the vision

Children's vision develops from birth to 8 years of age.

Fyour child has mystagmus, it is likely that we will offer negular orthoptic appointments to monitor their vision until your child is 7 or 8 years old. In addition to this, your child will be offered a glasses test every 12 months, unless the clinician requests you have this done some:

Fyour childs vision is significantly reduced by mystagmus, they may be suitable for sight impairment registration

If your childs vision is significantly affected by mystagmus, it may be helpful for your child and their teacher to have support at school / nusery to understand the condition and its implications in the classroom. This support can be provided by the visual impairment/ROVIC (rehabilitation officers for visually impaired children) team.

Fyouwould like any further information, please contact the orthoptic department on 01271322469
